Title of Project : Comprehensive study on environmental electrophiles-mediated signal transduction pathways regulated by reactive sulfur species

Yoshito Kumagai
(University of Tsukuba, Faculty of Medicine, Professor)

Research Area : Environmental and hygienic pharmacy

Keyword : environmental response, electrophile, chemical modification, signal transduction, reactive sulfur species

【Purpose and Background of the Research】

Environmental electrophiles covalently bind to thiol groups in proteins, such as sensor proteins, to form protein adducts, and this can lead to the development of cancer as well as injury to the surrounding tissue. However, very little is currently known about the mechanistic details of these phenomena and the role of environmental electrophiles in these processes. A variety of different cellular signal transduction pathways are known to be associated with homeostasis and the failure of cellular signaling can result in a number of physiological problems.

In the current study, we examine concentration-specific changes in the redox signal transduction pathways that are promoted by the activation of effector molecules coupled to the chemical modification of a sensor protein following the reaction of its thiol groups with environmental electrophiles. We also explore the possibility that reactive sulfur species such as hydrogen sulfide, persulfide and polysulfide would negatively regulate environmental electrophiles-mediated redox signaling processes.

【Research Methods】

As models for environmental electrophiles, we use with 1,4-benzoquinone, 1,4-naphthoquinone, methylmercury, cadmium, lead, acetaldehyde and formaldehyde. We examine (1) the development of a convenient assay for the detection of covalent modifications to the cellular proteins caused by their exposure to environmental electrophiles;

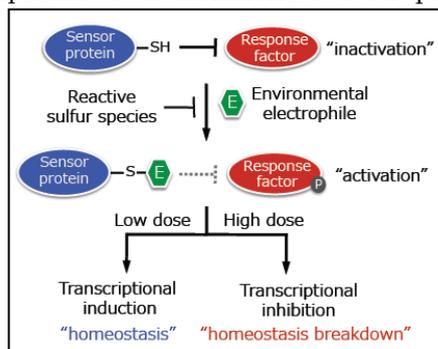

Fig.1 Modulation of environmental electrophiles-mediated the signal transduction pathways regulated by the reactive sulfur species

(2) the concentration-specificity during the activation and disruption of the signal transduction pathways following the exposure of cultured cells or experimental animals to environmental electrophiles; (3) the impact of the negative regulation of the reactive sulfur species on the environmental electrophiles-dependent modulation of the redox signal transduction pathways; and (4) the beneficial effect of phytochemical extracts containing the reactive sulfur species on the toxicities of environmental electrophiles in wild-type and CSE (an enzyme responsible for production of such reactive sulfur species) knockout mice.

【Expected Research Achievements and Scientific Significance】

Our rationale for this project is focused on our belief that environmental electrophiles are capable of modifying sensor proteins by reacting with their thiol groups, and that this could result in structural changes, thereby activating (under lower exposure) and disrupting (under higher exposure) the redox signal transduction pathways. It is noteworthy that reactive sulfur species react readily with environmental electrophiles, leading to the loss of their reactivity.
